

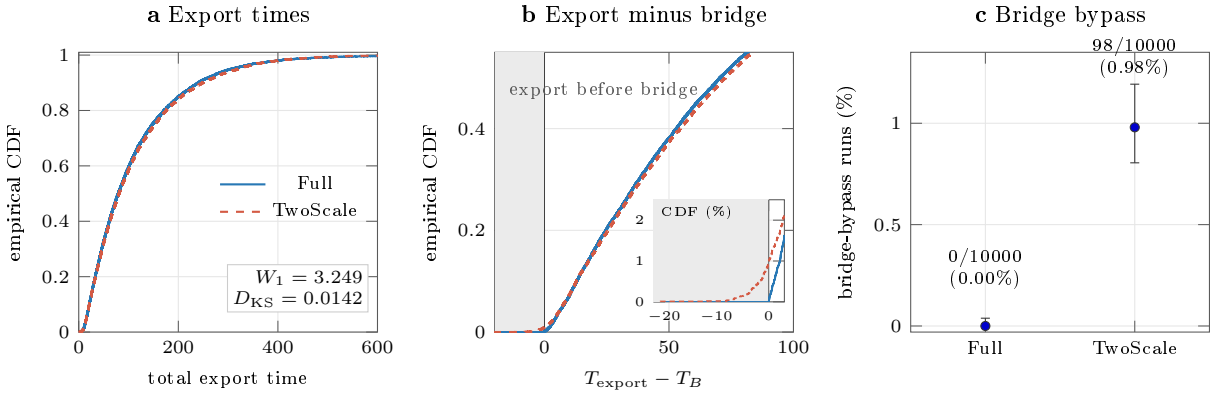

Figure 1: First export of infection in the clique–leaf network ($n = 100$, $k = 2$, $\beta = 0.005$, 10 000 runs of each model). (a) Empirical distribution functions of the export time. (b) Distributions of the difference $T_{\text{export}} - T_B$; negative values correspond to export before either real bridge node becomes infected. The inset magnifies the region near zero; its CDF values are shown as percentages. (c) Fraction of runs with this violation of the transmission order and 95% confidence intervals.
